| Execution           | 4 |

## SemaphoreCI

Semaphore is a cloud-based automation service for building, testing and deploying software. Whenever you push your code, Semaphore will automatically run your custom designed build, test and deploy pipeline.

Combining this with AutonomIQ's autonomous platform will revolutionise the entire phase of quality assurance of the product.

## Semaphore-Autonomiq

For helping with integration of Semaphore with Autonomiq, a sample integration file `semaphore.yml` has been provided in <https://github.com/Autonomiq/Connectors> under `.semaphore`. Other supporting code can also be referred to from there.

## Setup

Please refer to <https://docs.semaphoreci.com/> for more customisation on setting up Semaphore Continuous Integration for your product.

Listed below are some fundamental steps in setting up a sample project with Autonomiq

1. Navigate to your Semaphore web interface
2. Click on New and select the Git repository <https://github.com/Autonomiq/Connectors>
3. Modify `semaphore.yml` file under `.semaphore` folder as needed

Whenever a change is added to your commit this will be triggered,

## **Configuration file**

The configuration `semaphore.yml` file should be customised as per product requirement.

There are multiple blocks in the configuration file. Each consisting of different jobs. The commands listed under the jobs will execute your requirements of the job in sequential order.

For integration with AutonomIQ few files and commands need to be changed as per your product's requirement. This is listed below.

## **port\_forward.sh**

The port where your application is deployed in will be forwarded to Autonomiq's platform. For this below details should be filled.

Remote port - Remote port to which your application is to be forwarded to  
 app\_port - Port where your application is running

remote server url - For e.g.  
ubuntu@ec2-54-183-112-83.us-west-1.compute.amazonaws.com

## Command to execute

User has the freedom to execute testcases, test suite, excel/csv. Below is the base command and the customisations possible with it.

Base command:

**./sanitypython/bin/python test\_executor.py**

Add the following to the base command to execute the corresponding Case/Suite etc

| Suffix | Type                   | Format                   | Sample                           |
|--------|------------------------|--------------------------|----------------------------------|
| -f     | Files [Testcase files] | Filepath to csv/xls file | ./**/*.csv [Picks all csv files] |
| -su    | Suite                  | ProjectName SuiteName    | Geranium Regression              |
| -pr    | Project                | ProjectName              | Geranium                         |
| -r     | Recorder Files         | File path to JSON        | ./**/*.json                      |

Eg:

**./sanitypython/bin/python test\_executor.py -f ../other\_tests/test.csv**

**./sanitypython/bin/python test\_executor.py -su Geranium|Regression**

**./sanitypython/bin/python test\_executor.py -pr Geranium**

Other inputs can be

| Suffix | Type                                   | Format     | Sample  |
|--------|--|------------|---|
| -s     | Server - Endpoint for Autonomiq Server | URL        | <a href="https://google.com">https://google.com</a> |
| -u     | Username                               | Username   | someUser  |
| -p     | Password                               | Password   | somePassword  |
| -c     | Cleanup the temporary Project          | True/False | FALSE   |

Sample of the Autonomiq tests Block is given below. The changes in the command mentioned should be made here.

```
- name: "Autonomiq tests"
  task:
    jobs:
      - name: Autonomiq
        commands:
          - checkout
          - echo "make Autonomiq"
          - cd py
          - ./sanitypython/bin/python test_executor.py -f ../tests/test.csv
```

## Execution

The configuration file already has the setup to push the files to GIT once the tests have been triggered.

For further customisation for conditional executions such as pushing the code change only if there is no failure etc further changes in the commands needs to be done to the configuration file.

Once all the setup is done whenever there is any code commit, Semaphore will trigger all the blocks and subsequent tasks in the configuration file sequentially.

The status of this can be observed from Semaphore's web interface.

The screenshot shows the Semaphore web interface for a pipeline named 'Autonomiq Test example'. The pipeline consists of six sequential steps, all of which are completed successfully, indicated by green checkmarks:

- Build:** Docker build
- Smoke tests:** Smoke
- Unit tests:** RSpec, Lint code, Check security
- Integration tests:** Cucumber
- Autonomiq tests:** Autonomiq
- Push Image:** Push

The interface also shows the commit hash 'c4e214c' by user 'srihari33' and the time '26 Apr 23:36 · 03:44'. A 'Restart' button is visible in the top right corner.
